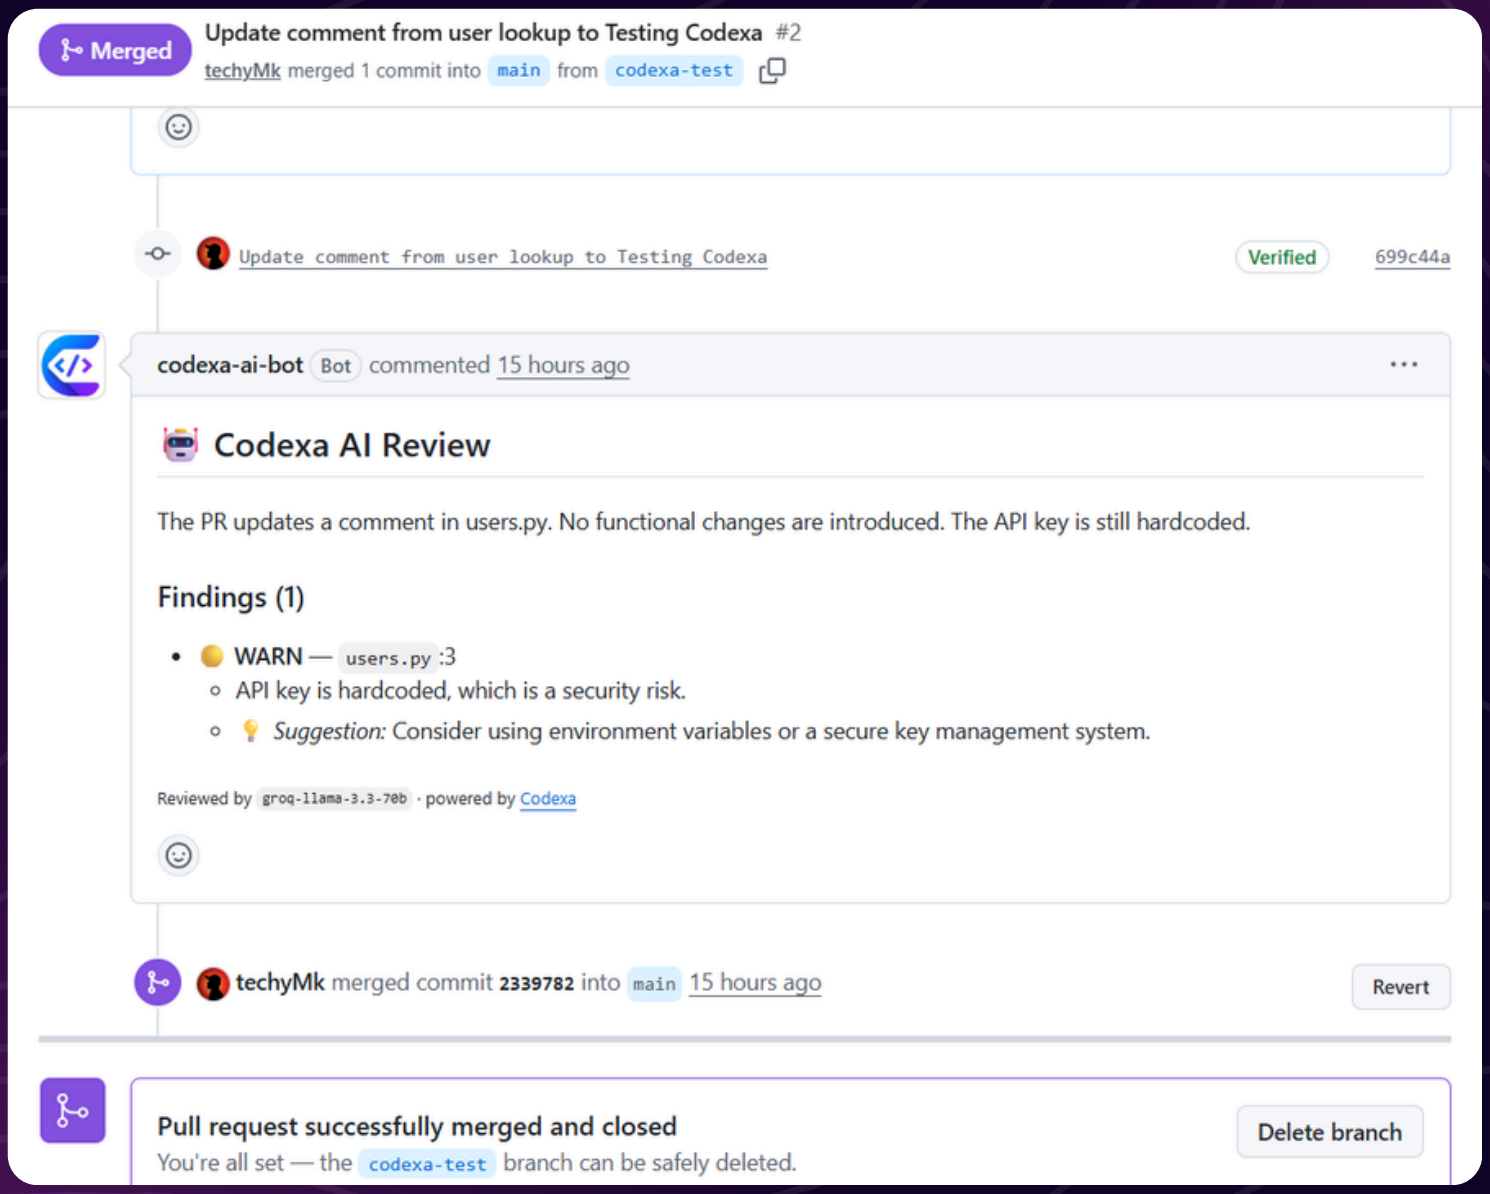
AI-POWERED CODE REVIEW



Real findings on a real PR.
Severity-tagged, actionable

5 errors · 0 warnings · 0 info

The PR introduces several security issues and potential bugs in the authentication helpers. The code is vulnerable to SQL injection, uses a broken hashing algorithm for passwords, and has a mutable default argument. Additionally, a production secret key is hardcoded and committed to source control.

Findings

- ERROR `auth.py`:5 — Hardcoded production secret key committed to source control, which is a significant security risk.
- ERROR `auth.py`:11 — MD5 is a broken hashing algorithm for password storage, vulnerable to rainbow tables and collisions.
- ERROR `auth.py`:17 — SQL injection vulnerability due to f-string interpolation into a query.
- ERROR `auth.py`:25 — Mutable default argument in the generate_token function, which can lead to unexpected behavior.
- ERROR `auth.py`:31 — Bare except clause swallows all exceptions, including KeyboardInterrupt, which can make debugging difficult.
